

Here is the file provided:

- 1) **httpd.conf.sample**: a simulation for Apache web server's configuration file

The purpose of this file is to test our C program in the linux environment.

Here is the execution screenshot.

```
cyuu@sand: ~/Courses/Fall2022/Compilers/HW5
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ ls
httpd.conf.sample  myscanner.c  myscanner.h  myscanner.l
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ lex myscanner.l
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ ls
httpd.conf.sample  lex.yy.c  myscanner.c  myscanner.h  myscanner.l
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ gcc myscanner.c lex.yy.c -o myscanner
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ ls
httpd.conf.sample  lex.yy.c  myscanner  myscanner.c  myscanner.h  myscanner.l
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$ ./myscanner < httpd.conf.sample
ntoken is 2
LISTEN_PORT is set to 8080
ntoken is 3
SERVER_NAME is set to localhost
ntoken is 4
LOG_LEVEL is set to warn
ntoken is 5
PHP_INI_DIR is set to php-8_1_10-Win32-vs16-x64
cyuu@sand:~/Courses/Fall2022/Compilers/HW5$
```

You need to study the Lecture 3 --- Lexical Analysis.

“The Tutorial on Lex\_Yacc.pdf”

Also, you need to run the code in **myscanner\_example.zip** to try to make sure you fully understand everything, including the tricks in the coding of the C program.

Your job is to develop the following and the submission is the exactly 3 files.

- A) **myscanner.c**
- B) **myscanner.h**
- C) **myscanner.l**

The 1<sup>st</sup> step, you will need to observe how your data looks like?

**[Hints]:**

**If you can check my zip file, there is one file “myscanner.l”.**

**In the middle of the content, the 2<sup>nd</sup> part, there are 2 parts actually.**

**It is the same in your homework, “myscanner.l”, 2 parts.**

```
return COLON;
return LISTEN_PORT;
return SERVER_NAME;
return LOG_LEVEL;
return PHP_INI_DIR;

return IDENTIFIER;
return INTEGER;
;
printf("unexpected character\n");
```

**As for this file, the “myscanner.l”, you need to do a good job in **regualr expression**.**

**At least, you need to match “php-8\_1\_10-Win32-vs16-x64”, this string.**

**Now, the last step is to develop your .c file:**

**You will need to switch on many “name token” (ntoken), but before the switch(){...}, you will need to get the “value token” (vtoken)**

**If there is a match of the ntoken we got previously, then do the further matching onto the vtoken.**

**The vtoken, you can just make it to match the **INTEGER** or **IDENTIFIER**.**

**By default, you can just put a “Syntax error...”.**

**Finally, do remember to use “yylex” to read the next ntoken again on the bottom of the while loop.**

**For, the running environment, I just use our “sand linux server”. That’s it!**
